ABSTRACT
The VANET security has become an important and active area within the research community. Despite the various attacks aimed at particular nodes in VANET that have been revealed, many attacks including multiple nodes still achieve little care. Furthermore, it might also have to do with the conception in which no taxonomy or survey has been performed to clarify the features of several multiple node attacks. This paper presents the aforesaid gap by offering a suitable definition and classification of Sybil attacks in VANET. In the suggested work GA has been employed with fitness function optimization. Genetic Algorithm can be utilized to invent elementary principles for networks traffic. At first, we establish a network according to our requirement, then show Sybil attack on the network and examine some particular parameters value on these attacks on the network which are provided as throughput, network load, end delay and packet delivery ratio. Then, we present genetic algorithm for optimization of fraud nodes then again examine the value depending on some particular parameters.

Keywords: VANET, Genetic Optimization Algorithm, Security.

I. INTRODUCTION
VANETs are one kind of mechanism to apply Intelligent Transportation System, which is a system designed for conveying communication technology as well as data in the direction of carrying vehicles as well as infrastructure[4,5]. The aforesaid is performed on IEEE 802.11p standard meant for Wireless Access intended for Vehicular Environment (WAVE). These networks have no fixed infrastructure; in summation to they are based on themselves for performing any type of network functionality

[6]. Security of vehicular networks is however principally a disclosed part. VANET, availability as a wireless network, take over altogether type of the security dangers which is a Wireless framework has to deal with. VANET security is Dangerous because a poorly considered Vehicular Ad hoc Network is susceptible to network attacks, also this know how to compromise the drivers of security [7,8]. A security framework must ensure which of the broadcast produces beginning a reliable source as well as it is not a tampered route by any other sources. It must also incursion a balance with confidentiality as for performing privacy as well as security consisted in a framework is inconsistent [9].

There are various kinds of possible attacks on Vehicular Ad hoc Networks [10, 11]. This one is critical in which Vehicular Ad hoc Network security should be skilled of maintaining each of the single kind of attack [12,13]. By Sybil attack is one of the serious attacks that has been discovered these days. Sybil attack is a type of security risk when a hub in a system confirms several features [16]. Most systems, same as a shared system, depend on considerations of personality, where each PC speaks to one character [14]. A Sybil attack occurs when an Unreliable PC is caught to claim various characters. Challenges reveal when a reputation system, (for instance, a record sharing reputation on a system) is betrayed into believing that an attacking PC has a disproportionately wide effect [15]. Correspondingly, an attacker with different personalities can use them to behave maliciously, by either taking data or interfering correspondence. Sybil attacks have showed up in various...
conditions, with wide uses for well being, security and trust. For example, a web survey can be static using many IP locations to represent countless. Some organizations have likewise used Sybil attack to enhance better appreciations. In this paper, Sybil attack prevention has been suggested utilizing genetic algorithm. The remaining paper is presented as Section 2 provides the detailed description of Sybil attack prevention in VANET. Section 3 consist the results and formulation in MATLAB and at last Section 4 consist conclusion and future scope.

II. RELATED WORK

[1] In this paper the author detects Sybil attack through cryptographic system. In this method a fixed key infrastructure is used for identifying Sybil attack. For reviewing the results of this study a Matlab simulator is used. There is very less delay in detecting Sybil attack in this method, as almost all operations are implemented in Certification Authority, so the proposed method is an efficient method for identifying Sybil attack. The only problem in this proposed method is that, when nodes prompt to other region the method does not work properly. [2] Fake messages and forge nodes are identified by observing their actions afterward of their sending out the messages by using the concept of data-centric Misbehavior Detection Schemes (MDS). In the data-centric MDS, Whether the received information is correct or not is decided by each node and it is made on the basis of consistency of recent received messages. There is no need of Voting or majority decisions, which makes MDS more reliable to detect Sybil attack. Once the attack is identified, Irrespective of revealing all the hidden ID of suspicious nodes, fine is imposed on those nodes and thus de-motivating them to act selfishly. Thus the computation and communication costs that were indulged in revealing all the hidden ID of suspicious nodes are reduced by this approach and the same is shown in the results. [3] In this a new timestamp series approach is suggested which is based on road side infrastructure. No special infrastructure or public key infrastructure is required in this approach. The case that two vehicles passes multiple RSUs simultaneously is uncommon, thus considering this assumption and impermanent relation between vehicles and RSU, two messages having identical timestamp series by same RSU will be taken as a Sybil attack by that vehicle.

III. SYBIL ATTACK

As VANET is an emerging research area and so are its security issues. There are many security issues in VANET but here in this section we will be dealing with one of its major security issue i.e the SYBIL ATTACK. SYBIL attack is a malicious attack in which the attacker creates multiple identities and uses them to gain a disproportionately large influence. SYBIL attack is very grievous as the attacker can play any kind of attack with the system scaling down the efficiency of VANET to a larger extent and thus making it less feasible for practical approach. These forge identities also creates a semblance that there are additional vehicles on the road. Thus the need of ensuring that any confidential information is neither modified nor misused by an attacker. For the prevention various strategies have been developed to prevent intruders from attacking the system. Some of it includes resource testing, public key cryptography, Passive Detection through Single Observer, Passive Detection through Multiple Observer, Propagation model, Active Detection by Position Verification, Sensor-Based Position Verification. Now we will discuss all of these one by one.

Resource Testing:- proposed by Douceur, this technique can be utilized to detect Sybil attack. It is based on the assumption that every single node has confined computational resources. But this technique has few limitations too. The first one is any malicious node may have more resources as compared to authenticated nodes. Secondly, this can bring out network congestion as there is a large number of replies/requests messages on the network.

Public Key Cryptography:- another mechanism of resolving Sybil attack is by the use of public key authentication. In this technique the digital certificates provided by TTP are combined with signatures utilizing the asymmetric cryptography. There is a CA for each region which issues certificates. The CA follows a hierarchy. The nodes communicate with each other by sending signed messages. The authenticated messages are kept and rest are ignored thus preventing Sybil attacker from intruding into the system. The problem with this approach is that it is very complex, time consuming and requires large memory.

Sensor-Based Position Verification:- malicious nature of the nodes is detected by using multiple sensors rather than using stationary infrastructure. The verification of the location information given by GPS system and detection of forge position information is done by using sensor data. The authentication of a node is done by calculating a trust value.

IV. DETECTION OF SYBIL ATTACK USING GENETIC ALGORITHM

This is the mechanism for detection of Sybil attack explained by the framework flow chart:
Step 1: Start

Step 2: obtain the network parameters from the provided VANET system. Every chromosome is then formulated for a fitness function by taking the different network parameters.

Step 3: Compute threshold \( T1 = \text{average} \ (\text{NPi}) \). Then the threshold is evaluated by computing the mean of the individual network parameters. Then the fitness criterion for each and every network parameter is evaluated

Where, \( T1 = \) First Threshold

\( \text{NPi} = \) Network Parameter i.e. network throughput, delay for \( I = 1, 2, 3, \ldots N \). \( N = \) Total no. of nodes in the network.

Step 4 : Encode chromosomes depending on threshold formulated.

Step 5 : Then Shortlist chromosomes depending on fitness,

\( \text{NPi} \leq T1 \) then \( \text{NPi} = 1 \) else \( \text{NPi} = 0 \).

Step 6 : Now, evaluate \( T2 \) as the weighted mean of the network parameters. Then the living Sybil nodes are the ones with the value of all the optimal parameters to be zero. Hence these nodes are found and plotted versus their node identification number.

Step 7 : Stop.

Below flowchart is the suggested mechanism to prevent network Sybil attack. The very first phase is the network parameters collection i.e. no. of rounds, no. of nodes, network width, and network length. After that network deployment happens that presents the data packets transmission from source to destination. After Sybil nodes detection takes place in the network. After this parameter formulation in Sybil attack takes place. Then employ genetic algorithm to examine these parameters so that Sybil attack prevention takes place. At last again parameter formulation has been done while examining with genetic algorithm. Optimization has been performed utilizing combination of fitness function and thresholding.

\[ T1 = \frac{1}{N} \sum_{i=1}^{N} \text{NPi} \]

\[ T2 = \frac{1}{N} \sum_{i=1}^{N} \text{NPi} \]

\[ \text{NPi} = \text{Network Parameter} \]

\[ \text{NPi} = \text{Network Parameter} \]

V. Conclusion

VANETs is quiet not secure as well as susceptible to various attacks so there is requirement of a proficient, dependable as well as a secured protocol which can be capable to rapidly organized and also use dynamic routing mechanism. Peer-to-peer systems play an ever-increasingly significant role of our daily life. Since, mostly peer-to-peer systems are susceptible to Sybil attacks. For designing more effective and practical Sybil defenses, we suggested an implementation depending on Genetic algorithm. In this paper, the challenges concerned to security i.e. Sybil attack has been studied. Then an Intrusion Detection System (IDS) particularly for Sybil attacks is implemented employing Genetic Algorithm, and then examined with networks of distributed node configurations.
